Market Risk - Synthetic Test

All numbers below are invented for software testing.

They are not market observations or investment advice.

Value at Risk (VaR) is a loss quantile at a confidence level.

Expected Shortfall measures average losses beyond that quantile.

Leverage can magnify portfolio losses in a stress scenario.

Synthetic portfolio stress results

Measure	Value	Unit
VaR at 99 percent	-1250.50	TRY
Expected Shortfall	-1875.75	TRY
Liquidity buffer	3200.00	TRY

Footnote: use the full table and its unit when citing a number.

Scanned Credit Risk Note

This page is a raster image and requires OCR.

Credit risk is the risk of loss from borrower default.

Probability of default (PD) is 2.00 percent in this example.

Loss given default (LGD) is 45.00 percent.

Exposure at default (EAD) is 100000.00 TRY.

Expected credit loss = PD x LGD x EAD = 900.00 TRY.

All values are synthetic; this is not a real credit assessment.
